INTRODUCTION

The use of indicator minerals for mineral exploration in glaciated terrain has evolved to a point where many different suites of indicator minerals, indicative of specific deposits types, are now being used (cf., Averill 2001; Lehtonen et al. 2015; McLenaghan & Paulen 2018, and references therein). These methods are particularly suited for reconnaissance surveys where heavy and mid-density indicator minerals collected from stream sediments and/or till allow a broad region to be assessed for the presence of potential mineral deposits. As part of the Geological Survey of Canada’s (GSC) Geo-mapping for Energy and Minerals (GEM-2) Program (2013-2020), the Southern Mackenzie Surficial activity (2017-2020) collected stream sediments and till samples across a 35,000 km² region and examined their heavy mineral content. This research activity is being conducted in a region with no prior surficial mapping and very limited surficial sampling for heavy minerals by Cominco Limited in the early 1980s (mostly industry-confidential data; cf., Brabec 1976, 1983; Lane 1980). Despite hosting the past-producing world-class Mississippi Valley-type (MVT) Pine Point Pb-Zn district, almost no other mineral showings have been reported in this extensive region, despite significant interpreted potential for additional mineral resources, and extensive reports of Pb-Zn mineralization at depth (Hannigan 2006a). In this technical article, we provide new results which illustrate the potential for new, undiscovered targets in the region, and further highlight how heavy mineral assemblages and geochemical and isotopic compositions are powerful tools for exploration in glaciated regions (Paulen et al. 2017, 2018; Day et al. 2018a; King et al. 2018).

Location and Physiography

Surficial mapping, targeted surficial geology studies, and stream sediment and till sampling for geochemistry and heavy mineral indicators were initiated in 2017 in the southern Northwest Territories (NWT) of northern Canada (Fig. 1). Samples were collected between 114°W to 124°W longitude, east of the Liard River, and from 60°N along the Northwest Territories – Alberta provincial border to 62°N latitude. Surficial mapping was focussed within National Topographic Map sheets (NTS) 85-C, F, and G.

The district lies in the Great Slave Plain and Alberta Plateau physiographic regions of the Western Interior Plains (Bostock 1970) and is relatively flat, other than the Cameron Hills upland area along the southern part of the study area. The vegetation is typical of the northern Boreal forest of Canada; black spruce bogs and open fens in the poorly-drained lowlands with poplar and jack pine forests in upland regions that have better drainage.

Bedrock and Surficial Geology

This study area is situated in the Western Canada Sedimentary Basin (WCSB), which consists of a wedge of Phanerozoic sedimentary rocks that overlap the Precambrian

Figure 1. Study area for surficial mapping and heavy mineral studies, southwest Northwest Territories, Canada. The study area is contained within the WCSB, underlain by Paleozoic carbonate (white) and Cretaceous (pale green) bedrock, west of the Canadian Shield and east of the Cordilleran deformation. Arrows indicate direction of regional ice flow of the Laurentide Ice Sheet that impacted the area; ice-flow vectors from Prest et al. (1968); Kerr (2006); Bednarski (2008), Huntley et al. (2008), and ice-flow history at Pine Point from Oviatt et al. (2015), arrow sizes indicate relative erosional vigour, and numbers indicate relative ice-flow chronology.

craton and thicken westward towards the deformed belt of the Cordillera (Fig. 1; Porter et al. 1982; Okulitch 2006). The Precambrian crystalline basement rocks are overlain by Lower and Middle Devonian sedimentary rocks, primarily platform carbonates which contain the Presqu’ile dolomitized complex that hosts to the Pine Point MVT district (Rhodes et al. 1984; Meijer Drees 1993). Two significant sedimentary successions constitute the fill of the WCSB. The older and deeper succession consists dominantly of Paleozoic marine carbonates which were later buried by shallow marine and nonmarine clastic sediments of Mesozoic age (Douglas 1959; Richards 1989).

Both sedimentary successions have been affected by cratonic arching and faulting in the underlying crystalline Proterozoic basement. In southern Northwest Territories this faulting is most prominently displayed by the northeast-southwest trending Great Slave Lake Shear Zone and other subparallel faults (Eaton & Hope 2003). Upper Devonian rocks are composed of thick shale (up to 1.5 km), which are locally pyritic and bituminous, and are interbedded with reeval carbonate beds. Shallow-dipping Cretaceous sandstone, siltstone and shale dominate the southern part of the study area and consist of upper and lower Cretaceous units that unconformably overly Paleozoic strata (Dixon 1999). In 1998, kimberlites were discovered near Fort Simpson, hosted in Upper Devonian bedrock (Pitman 2014).

The study area was inundated by the Laurentide Ice Sheet (LIS) during the late Wisconsin glaciation (∼24-10 14C ka BP; Dyke & Prest 1987; Dyke 2004). Predominant glacially streamlined landforms (flutings and drumlins) indicate a southwest ice flow across the study area. At Pine Point, 70 km east of Hay River town site, bedrock striae (Oviatt et al. 2015) and clast fabric measurements (Rice et al. 2013) record at least 3 ice flow trajectories: earliest to the southwest (230°), intermediary to the northwest (300°), and a final west-southwest (250°) flow (Fig. 1). West of Hay River, LIS flow was influenced by the rising topography of the Cordillera and was deflected south-southwestward across the Cameron Hills and Trout Lake uplands, and northward down the Liard and Mackenzie river valleys (Bednarski 2008).

During deglaciation, retreating ice became increasingly topographically confined and prominent lobes extended south and west down the Hay and Mackenzie river valleys, respectively. Ice retreated from the study area between 11-10 14C ka BP (Dyke 2004). Blockage of regional drainage and impoundment within glacioisostatically depressed basins led to the formation of glacial Lake McConnell along the retreating ice margin (Lemmen et al. 1994). After 8.5 14C ka BP, glacial Lake McConnell continued to drain largely through a process of decantation by glacioisostatic uplift (Lemmen et al. 1994; Smith 1994). The study area is blanketed by thick till deposits (>20 m thick; Smith & Lesk-Winfield 2010), with local thicknesses infilling karst collapse structures exceeding 100 m. The rim of the Devonian platform carbonates paralleling the southwest shore of Great Slave Lake are the only exposed bedrock at surface. Where areas were submerged by glacial Lake McConnell, an often prominent, thin (<50 cm) winnowed till and cobble-boulder lag is found. Accumulations of glaciolacustrine sediments are generally thin, with thickest deposits found around the western and southern shores of Great Slave Lake. The modern surface is covered by expansive peat bogs and fens, underlain by discontinuous permafrost displaying widespread active thermokarst (Paulen et al. 2017).

Rationale and Background
The impetus to conduct heavy mineral studies in the southern NWT was the identified base metal mineral potential reported by Hannigan (2006a), as well as positive results from several adjacent heavy mineral surveys conducted in regions underlain by Paleozoic and Cretaceous bedrock, for which there was no known surface bedrock mineralization (Plouffe et al. 2006; McCurdy et al. 2007), and the recent discovery of kimberlites and abundant kimberlite indicator minerals (Day et al., 2007; Pitman, 2014).

Research conducted during the GSC’s Targeted Geoscience Initiative (TGI) project investigating the potential for MVT mineralization in northern Alberta and the Great Slave Plain of southern Northwest Territories (Hannigan 2006a) produced a mineral prospectivity map showing MVT mineralization potential in the carbonate platform of the southwest Great Slave Lake region around and west of the Pine Point mining district (Fig. 2; Hannigan 2006b). Concurrently, a two-year reconnaissance stream and glacial sediment sampling project, funded by Geoscience BC and the GSC in northeastern British Columbia documented elevated values of Pb and Zn in till and stream sediment samples (McCurdy et al. 2007) about 400 km west-southwest of Pine Point.

Figure 2. Mineral prospectivity map of the southern Northwest Territories, with ratings for the potential to host MVT mineralization (from Hannigan 2006b, p. 339).

continued on page 6
The GSC, under the Northern Resource Development Program (2003-2007), and the Alberta Geological Survey, also funded a surficial mapping and reconnaissance till sampling program in northwest Alberta that led to discovery of a significant sphalerite dispersal train in the Zama Lake lowlands, 300 km southwest of Pine Point (Fig. 3; Plouffe et al. 2006; Paulen et al. 2011). Historically, the Cretaceous sedimentary rocks of the WCSB renowned for their hydrocarbon resources, in which these two independent studies documented elevated Pb and Zn concentrations, have seldom been considered to have potential to host base metal mineralization (MacQueen 1997).

Based further on the reconnaissance study results in neighbouring British Columbia and Alberta, a stream sediment and till heavy mineral sampling program was included in the Protected Area Strategy (PAS) studies in the Sambaa K’e (Trout Lake; Watson 2011a) and Ka’a’gee Tu (Kakisa Lake; Watson 2011b) regions. Results from these PAS surveys identified significant elevated abundances of sphalerite, galena, and chalcopyrite in till samples overlying Paleozoic carbonate and Cretaceous sedimentary rocks (Fig. 4).

Figure 3. Number of sphalerite grains in the 0.25-0.5 mm heavy mineral fraction (normalised to a 30 kg till sample mass) recovered from till samples in northwest Alberta and the delimited dispersal train (bounded by the thick black dashed lines) plotted on hillshade digital elevation model from Shuttle Radar Terrain Model (SRTM) of northwest Alberta (modified from Plouffe et al. 2008). Small white circles represent a single grain; small solid black circles indicate samples with no sphalerite. The highlighted light gray zone marks the approximate location of the Great Slave Lake shear zone (GSLSZ; Eaton and Hope 2003) projected to surface (modified from Paulen et al. 2011).
New base metal mineral potential... continued from page 6

Figure 4. Number of chalcopyrite grains in the 0.25-2.0 mm heavy mineral fraction (normalised to 25 kg of <2 mm table feed weight) recovered from till samples in the Trout Lake (left) and Kakisa Lake (right) PAS surveys (Watson 2011a, b). General glacial ice flow direction here was from northeast to southwest. Classification intervals were arbitrarily assigned to the control variation in the number of grains per sample. Bedrock geology modified from Douglas (1974) and Okulitch (2006).

Drift prospecting research conducted around deposits within the Pine Point district under the GSC’s GEM-1 Program (2008-2013) demonstrated that indicator minerals methods applied to till and stream sediments are effective tools for MVT exploration. The main indicator minerals, galena and sphalerite, survive glacial and fluvial transport and post-glacial weathering in this carbonate terrain (Oviatt et al. 2013, 2015; McClenaghan et al. 2018). Another important observation from their research was that chalcopyrite was not recovered in till or streams immediately down ice of from the Pb-Zn deposits.

METHODS

PAS indicator mineral analysis

Under the previous PAS surveys (Watson 2011a, b, 2013), numerous sand-sized (0.25–2.0 mm) grains of sphalerite, galena, chalcopyrite, and arsenopyrite were recovered from sediments. These mineral grains were donated by the Northwest Territories Geological Survey (NTGS) to the GSC for inclusion in this study. Note, indicator mineral results discussed for the PAS till samples have been normalised to a 25 kg table feed weight. In the previous PAS study, sphalerite, which ranges in colour from red to orange to black, was recovered in 57...
samples with the highest count per sample being 334 grains. Chalcopyrite grains (n≤31) were picked from 135 samples (Fig. 4). Several of the till samples containing sphalerite also contained galena and arsenopyrite grains, complete results of which are reported in King et al. (2018).

In this study, the donated sphalerite, galena, chalcopyrite, and arsenopyrite grains were mounted in 25 mm circular epoxy mounts and carbon coated. Imaging and semi-quantitative mineral compositions were determined using scanning electron microscopy (SEM) and energy dispersive spectrometry (EDS). These grains were then further analyzed for Pb and S (δ34S) isotopes using secondary ion mass spectrometry (SIMS). Details of SEM and SIMS work for are outlined in King et al. (2018).

GEM-2 stream sediment survey

Stream sediment samples collected as part of this activity followed the GSC’s former National Geochemical Reconnaissance (NGR) programme’s protocols for sample collection and analysis, in order to ensure consistent and reliable results, regardless of the area, date of the survey, or the analytical laboratory used (Friske & Hornbrook 1991). Bulk stream sediment, silt sediment, and water samples were collected from 31 sites in 2017 and 8 sites in 2018 (Day et al. 2018b). At each stream sample site, an on-site (0.45 μm) filtered water sample, a grab sample of silt-sized sediment, and a wet-sieved (<2 mm) bulk sediment sample were collected. The wet-sieved bulk sediment samples were processed to obtain the HMC fraction, from which indicator minerals, including sphalerite and galena, were counted, and representative grains picked. Indicator mineral grains of interest will be analysed to obtain their chemistry and isotopic composition which will assist in determining bedrock source and mineral potential.

GEM-2 till heavy mineral survey

Samples of till were collected throughout the study area at an approximate 10-15 km spacing for NTS sheets 85C, 85F and 85G. Additionally, samples were collected along two transects from east (up-ice) of Pine Point to the Liard River, to test for potential long-distance transport of MVT indicator minerals from Pine Point. Till samples were collected from 137 sites in 2017 and 54 sites in 2018 (Paulen et al. 2018).

Sample sites were located opportunistically along the few highway and trails that bisect the study area, but were largely conducted by helicopter, where landing areas were found often with great difficulty in former forest burn sites, or along the margins of bogs, fens and lakes. Till sample collection and quality control guidelines followed established GSC
New base metal mineral potential... continued from page 9

till sampling and analytical protocols (Spirito et al. 2011; McClenaghan et al. 2013; Plouffe et al. 2013). A bulk sample of till (~25 kg) was collected for heavy mineral concentrate (HMC) processing using the methodology outlined by McClenaghan (2011) and similar to that used for the stream sediment samples.

PRELIMINARY RESULTS AND INTERPRETATIONS

PAS indicator mineral analysis

Sulphur and Pb isotope data and interpretations of the PAS survey galena grains in till samples are presented in King et al. (2018). In summary, the galena grains have $^{206}\text{Pb}/^{204}\text{Pb}$ ratios ranging from 18.00 to 18.20 and $^{207}\text{Pb}/^{204}\text{Pb}$ ratios ranging from 15.58 to 15.71. These cluster proximal to the shale curve, a crustal Pb isotope curve that is representative of local basement in western Canada (i.e., western Laurentian continental crust; Fig. 5; Godwin and Sinclair 1982; Cumming et al. 1990). Such Pb ratios are indicative of an evolved upper crustal source; however, they have a more radiogenic Pb signature than Pine Point district samples, suggesting that the fluids responsible for the formation of the PAS galena grains tapped separate, older, more radiogenic Pb sources (e.g., Zartman & Haines 1988; Cumming et al. 1990; Kramers & Tolstikhin 1997).

Secondary ion mass spectrometry (SIMS) $\delta^{34}\text{S}$ values for galena range from +0.63 to +26.87‰, like the values found in previous studies at Pine Point, indicating galena grains have a similar sulphur source to Pine Point (Kyle 1981; Oviatt et al. 2015). Chalcopyrite has $\delta^{34}\text{S}$ values ranging from -20.64 to +28.33‰ and arsenopyrite has $\delta^{34}\text{S}$ values ranging from -2 to +2‰. The $\delta^{34}\text{S}$ values found in chalcopyrite are similar to...
New base metal mineral potential... continued from page 10

Figure 6. Histogram of \( \delta^{34}S \) values of PAS survey chalcopyrite (blue; King et al. 2018) compared with values from Manto-style mineralization in Peru (red; Ripley and Ohmoto 1977), the Tom sedimentary exhalative (SEDEX) deposit in the Yukon Territory (yellow; Gardner and Hutcheon, 1985), the Blende carbonate-hosted Pb-Zn deposit, Yukon Territory (grey; Robinson and Godwin 1995), and sediment-hosted Cu deposits in Africa (orange; El Desouky et al. 2010).

sediment-hosted Cu deposits and chalcopyrite from magmatic hydrothermal Manto-type deposits, suggesting potential for either deposit type in the region (e.g., Ripley & Ohmoto 1977; El Desouky et al. 2010). Arsenopyrite \( \delta^{34}S \) have values similar to igneous rocks (e.g. \( \delta^{34}S = 0 \pm 3\% \); Ohmoto & Rye 1979; Ohmoto & Goldhaber 1997), which could indicate that sulphur in arsenopyrite grains was derived from igneous basement rocks. Additionally, orogenic gold deposits near Yellowknife contain arsenopyrite that have \( \delta^{34}S \) values similar to those in the PAS samples, suggesting that the arsenopyrite grains from the study area may be sourced from orogenic Au systems hosted in the Canadian Shield, well (>250 km) up-ice of the region (Wanless et al. 1960; Marini et al. 2011).

GEM-2 stream sediment survey

Results for 31 samples collected in 2017 were published in Day et al. (2018a). In order to counter potential sample bias due to the hydrodynamic forces active within a flowing stream and variability of HMC content of stream sediments within and between sites (cf., Prior et al. 2009), the indicator mineral counts for stream sediments were normalised to the weight of the heavy mineral fraction rather than the weight of the total sample (<2 mm table feed). Mineral grain plots presented here are values normalised to the weight of the heavy mineral fraction, plotted on a bedrock base map (Okulitch 2006); legend for the bedrock base is provided in Figure 7.

The highest grain counts for sphalerite ((Zn,Fe)S) plus galena (PbS) reported in stream sediments (Day et al. 2018a) is a site on the Buffalo River, approximately 20 km down-ice (west) of the closest known subcrop of mineralization in the Pine Point mining district (Kyle 1981; S. Clemmer pers. comm., July 2018). This sample contains one of the highest number of grams ever reported for a GSC NGR regional heavy mineral survey in northern Canada with more than 6000 grains of sphalerite and 40 grains of galena (Fig. 8a). Large numbers of sphalerite grains were also recovered from stream sites along NE-SW structural trends parallel to, and between, the Trout Lake Fault Zone and Tathlina Fault Zone, >200 km west of the Pine Point district. Elevated counts of galena (60 grains) were also obtained on the Hay and Kakisa rivers, ~75 and 150 km, respectively, down-ice from the Pine Point district (Fig. 8b).

Chalcopyrite (CuFeS_2) abundance in stream sediments (Fig. 9a) shows an arcuate 200 km trend of elevated values from the Hay River to the Mackenzie River. Scheelite (CaWO_4) is a mineral which was not be expected to be present in stream sediment HMCs because of the underlying bedrock geology. Scheelite is physically robust and known to survive

continued on page 12
New base metal mineral potential… continued from page 11

Figure 7. Legend for bedrock geology of the Western Canada Sedimentary Basin between the Canadian Shield and Cordillera used in Figures 8 and 9. Note that the bedrock geology is shown projected under the lakes (after Douglas 1974 and Okulitch 2006). Major fault systems and mineral occurrences are also noted.

Figure 8. Number of (A) sphalerite grains and (B) galena grains in the 0.25-0.5 mm heavy mineral fraction (normalised to a 50 g heavy mineral fraction weight) recovered from stream sediment samples in the 2017 GSC GEM stream sediment survey (Day et al. 2018a). The large black rectangle is the Pine Point mining district containing >100 Pb-Zn ore bodies distributed over 1600 km² (Hannigan 2006b). See Figure 7 for bedrock legend.
New base metal mineral potential… continued from page 12

Scheelite grain counts are highest along a trend parallel to the Rabbit Lake Fault Zone immediately west of Kakisa Lake (Fig. 9b).

**GEM-2 till heavy mineral survey**

Indicator mineral counts have yet to be published for the 191 till samples collected in the study area. However, chalcopyrite occurs in more than 90% of the till samples west of Hay River and east of the Trout Lake PAS survey, and there are additional sites with elevated sphalerite and galena grains more than 150 km west of Pine Point. Publication of results from the 2017 survey are anticipated in early 2019.

**DISCUSSION**

Sphalerite and galena mineralization has long been known and exploited in the past-producing Pine Point Pb-Zn mining district. Carbonate-hosted sphalerite and galena outcrop and subcrop beneath till in the Pine Point area; however, to the west of the Hay River there are no documented occurrences of bedrock mineralization exposed at the bedrock surface, only reports of sphalerite and galena mineralization at depth in drillcore (Hannigan 2006a). This is important to note, because galena and sphalerite could only be incorporated into the glacial and post-glacial sediments if the bedrock mineralization subcrops and was exposed to an overriding glacier. A single Pb-Zn mineral occurrence, Qito, is located near the northern limit of the study area, on the west side of Great Slave Lake, on the Rabbit Lake Fault Zone and is described as galena and sphalerite mineralization hosted in Presqu’ile dolostone (Turner 2006). This site is >100 km to the northeast of the nearest stream sediment anomaly near Kakisa Lake. The presence of elevated sphalerite and galena grain counts in stream sediment HMCs documented in this study, distal to Pine Point district, is significant in that it implies that the Laurentide Ice Sheet eroded sphalerite and galena mineralization exposed at bedrock surface at unknown sources. Mineral-rich glacial sediments were deposited, which were subsequently reworked into local stream sediments.

continued on page 14
EXPLORATION TARGETS

Preliminary S and Pb isotope data from galena grains in regions around Trout and Kakisa lakes indicate that grains are from proximal sources and not dispersed from Pine Point (King et al. 2018). Based on the similarity of the δ34S values for galena grains from the PAS surveys to those from known MVT deposits, the galena in the study area likely originated from MVT-style mineralization. Glacial dispersal studies in the Pine Point mining district by Oviatt et al. (2015) and McClanaghan et al. (2018) showed that 700 m down-ice from mineralization, till samples generally contain tens of grains of galena, which is a reflection of the low hardness of galena (2.5–3) and its brittle nature due to its cubic cleavage. Galena rarely survives glacial transport beyond 1 km because of its softness. Thus, it is assumed that the galena grains in the PAS till samples are locally derived (i.e., likely <1 km from their source). As previously suggested by Hannigan (2006b), Pb-Zn exploration should be focused in carbonate units proximal to the faults in the region, including the Trout Lake, Rabbit Lake, and Tathlina fault zones, as well as the Cameron Hills structure (Fig. 4).

Chalcopyrite found in tills throughout the study area may have been sourced from sediment-hosted Cu mineralization, as indicated by the significant variations in δ34S values, a feature found in sediment-hosted Cu deposits globally (Leblanc & Arnold 1994; El Desouky et al. 2010). The presence of chalcopyrite grains in the PAS till surveys in the Trout Lake-Kakisa area (Fig. 4) pose an intriguing question of provenance. Bedrock lithologies underlying the study area are essentially an undeformed sedimentary package of Paleozoic carbonates and Mesozoic shales, siltstones and sandstones cross-cut by the NE-SW trending Great Slave Lake Shear Zone and several significant subparallel fault structures (Eaton & Hope, 2003). A single Cu-Zn mineral occurrence, Moisey, is located within the study area, adjacent to the Liard River, and is described as Kipushi/Manto-type mineralization hosted in the carbonate and shale units of the Upper Devonian Fort Simpson Formation (Dudek 1993). Note, the Moisey site cannot be the source of the elevated HMC chalcopyrite grains as it is situated glacially down-flow, at the western edge of the study area. The arcuate chalcopyrite trend is either coincident with, or is proximal to the same host lithologies and warrants further investigation as to whether the chalcopyrite grains recovered from the stream sediment HMC samples are genetically related.

Arsenopyrite grains have δ34S values similar to orogenic Au deposits near Yellowknife (400 km to the northeast), indicating grains found in the study region may have been sourced from similar deposits up-ice of this region (Wanless et al. 1960). The significance of scheelite in the stream sediments is undetermined; however, future mineral chemistry studies may shed light on bedrock provenance and potentially glacial transport history.

FUTURE WORK

In addition to in situ isotope methods, δ34S isotopes of sphalerite, chalcopyrite and galena grains in till were measured at the University of Ottawa G.G. Hatch Stable Isotope Laboratory. Full interpretations of δ34S and Pb-isotopic data from PAS survey samples will be available in future GSC publications. On-going research at Memorial University will provide additional δ34S, Pb, and geochemical data from GEM2 GSC till and stream sediment samples (Paulen et al. 2017, 2018; Day et al., 2018a, b).

Future work will include SEM-EDS, EPMA, LA-ICP-MS, SIMS and conventional sulphur isotope work on sulphide phases including sphalerite, galena, chalcopyrite and arsenopyrite grains recovered from 2017 till and stream sediment samples. Several bedrock samples collected from the Pine Point district will also be used in conjunction with data from previous studies (Oviatt 2013; Oviatt et al. 2015), along with bedrock and drill core samples from other mineral occurrences in the area, to compare potential source regions for sulphide species recovered from surface till samples. Mineral chemistry studies also will be undertaken on scheelite grains, so as to determine potential bedrock sources of the scheelite and deposit type of origin (e.g., Poulin et al. 2018).

Geological Survey is thanked for providing the PAS base metal indicator minerals for analyses. The authors would like to acknowledge Glenn Piercey and Dr. Graham Layne (Memorial University) for SIMS Pb and S isotopic analysis. Additionally, Dr. Wanda Aylward (Memorial University) is acknowledged for assistance with preliminary SEM imaging and analysis. Additional support for grant analysis is provided by a NSERC Discovery Grant to Stephen Piercey. Assistance with all aspects of fieldwork was cheerfully provided by GEM-2 funded students Grant Hagedorn (University of Waterloo), Robert King (Memorial University), Joeli Plakhmoh (Carleton University) and Jamie Sapera (Brock University). Excellent assistance in the field and wildlife monitoring was provided by Irene Graham and Pat Martel (Kàt’léodeeche First Nation), Darcy Simba (Kaat’gée Tu First Nation) and Henry Sabourin, James Nadli and Alan Farcy (Deh Gah Got’ie Koe First Nation). David Huntley (GSC Vancouver) and EXPLORE editor Beth McClenaghan are thanked for critical reviews of earlier drafts of this paper.
